Acknowledgement

We would like to take this opportunity to express our gratitude to the people who have lent their support all along this thesis and thus enabled us to concentrate on our work. Foremost, we would like to express our sincere gratitude to our supervisor Dr. Noel Fernando for the continuous support to our final year research. His patience, motivation, enthusiasm, and immense knowledge helped us very much in doing our research. His guidance helped us in all times of the research and in writing of this thesis. We would like to thank Mr. Thushan Gunawardhane, Mr. Sanjeth Srikathirkamanathan and Mr. Amith Dissanayake for their insightful comments, hard questions, immense support and encouragement as advisors during our research duration. We also thank our 4th year fellow mates, for stimulating discussions, for the sleepless nights we were working together before deadlines, and for all the fun we have had in the last year. Last but not the least, our families and friends for continuous support and encouragement throughout the year.

Abstract

Traveling and tourism is a world-leading industry. Having a competitive price is crucial to survive in the current competitive environment. This study is related to forecasting better prices for a railway based tourism company located in the European region, by considering the past sales patterns with the external factors such as weather, season and holidays. Currently, they are deciding their prices by past experiences.

The dataset received contained all products of flam railway and by preprocessing and feature extraction relevant records were chosen only relating to flam railway. Extracted data was combined with external data such as weather, season and holidays which were collected from APIs. Then trip packages were identified and dataset was broken based on different packages.

In this research researchers try to evaluate and compare the performance of various models traditionally used for price prediction. Here performance of Deep Neural Network, Ordinary Least Squares Multiple Linear Regression Model (sklearn), SARIMAX Model, Ordinary Least Squares Multiple Linear Regression Model (statsmodels), Support Vector Machine and Extreme Learning Machine was evaluated. Root mean square error was used to compare the performance of the models. Model with least root mean square error was selected to predict the price of the model.

75 packaged had Deep Neural Network as the best performing model while 11 and 3 packages had Ordinary Least Squares Multiple Regression (statsmodels) Model and Linear Regression Model (sklearn) respectively.

The hybrid model was created using above models, deflated price and respective sales volume. Estimated increase of revenue when using the better price of the hybrid model had a maximum of 120.59% increase, minimum of 12.12% increase and average of 79.25%

Chapter 1

Introduction

1.1 Background of the Problem

There are various platforms including Book Visit by Visit Group, where service providers can list their packages and trips to attract customers. Currently they have to set their prices using past experience and expertise knowledge. At present there is no method to get price suggestions based on sales patterns in seasons, weather, holidays etc. But a huge volume of data is available in this domain. Furthermore these prices may change due to external factors such as weather, holidays, seasons etc. which cannot be derived by analysing only historical data. So identifying a better price based on sales patterns is an important timely problem in the current context.

1.2 Problem Statement

Europe Railway Tourism Company 'Visit Flam' is currently estimating the price for their railway tourism trips manually. Sometimes Visit Flam does not achieve a good revenue from their railway tourism trips by using the manually estimated trip prices. Europe is an area where there is rapid weather and seasonal changes. Therefore these factors also affect how people go on trips. Therefore it is a necessity for them to predict a better price for their trip packages by also analyzing weather, season and holiday data. Therefore by analysing and detecting hidden sales patterns and external information including weather data, seasonal data and holidays, we can successfully forecast a better price to the service provider. Thereby the service provider can gain a competitive advantage over other competitors. If we can address this problem Visit Flam can achieve a significant revenue, reputation and customer base increase.

1.3 Research Questions

1. Research Q1: What are the current techniques for pattern recognition, business intelligence and forecasting better prices?
2. Research Q2: What are the gaps in the current techniques described in Research Q1 with respect to forecasting better prices based on sales patterns considering related factors in Europe railway tourism?

3. Research Q3: How to propose a better price model to forecast prices based on sales patterns to the Europe railway tourism to overcome gaps in Research Q2 by considering the other factors?

1.4 Significance of the Research

Many travel providing companies and even railways can adopt this research approach of price prediction for their trips. This approach will be suitable for trips of any country as weather, season and holidays definitely affect the participation of passengers or tourists in trips in any country. Even the Sri Lankan Railway can get a better price for the train journeys based on these external factors. We also suggest that rather than just manually giving a price to a journey or a trip it is better to take other factors which influence the trip or journey into account when giving a trip or journey price.

A major significance of this research is that for any trip or journey this research approach and the models could be adopted to give a better price for the trip or journey. Not only for train trips but even for bus trips this research approach and models could be implemented.

1.5 Research Approach

This research will take a quantitative research approach to meet the main objective of the project which is to forecast a better price using the generated models. Different models will be evaluated quantitatively so that a fair comparison can be done among them. This will allow the researchers to identify the shortcomings of each model in the current context of the research and to measure the effectiveness of each model. The machine learning models used are Deep Neural Network, Extreme Learning Machine and Support Vector Regression. The statistical models used for price prediction are time series model, linear regression and ordinary least squares model. A hybrid model was built by taking the best features from the models. Root mean square error was taken in choosing the best model. Hybrid model will be able to predict a better price for all the 89 trip packages by considering the external factors which are weather, season and holidays.

1.6 Limitations, Delimitations and Assumptions

1.6.1 Limitations

1. The prediction is based on the data set provided by the Norway based train tour company.
2. The data is based on only for the recorded daily trips based on several locations following 89 trip packages.
3. Trip requests for certain trips are not considered and only the participated trips are considered.
4. Base fee for a train ride for the certain package is considered as the Trip Price but other expenses are not considered.

5. Weather (Average Temperature ,Snow Fall, Sun Hour and UV Index), Holidays and Seasons are only considered as the external factors.

1.6.2 Delimitations

1. Only applies to destinations of Flam Railway.

1.6.3 Assumptions

1. All trips chosen only contain train travel between stations.
2. Lowest price for each trip was taken assuming it only contains train travel.

1.7 Contribution

We contribute following to the research community,

- Comparison of various models used to predict the price of a package using not only historic data but also external factors such as weather, season and holidays.

Furthermore we deliver the following to the research community for future research in this area.

- A script to generate the whole journey of a trip from trip legs.
- A script to identify least price for the day and substitute it as price for all trips in that package for the day.

1.8 Remaining Chapters

Chapter 2 is the Literature Review and Background chapter and it shows what are the current models available for price prediction and the limitations of the current models. Also Chapter 2 has a description about Flam Railway. Chapter 3 is the methodology chapter and it explains the research design and the research approach. Chapter 3 shows how data was collected and pre-processed and descriptions of the models that were used for predicting a better price. Chapter 4 is the results chapter and it shows the results we got from each model and also the relationships between variables we identified when pre-processing. Chapter 5 is the discussion chapter and it discussed the results of the results chapter and also the findings from our research. Chapter 5 contains also the conclusion of our research.

Chapter 2

Literature Review and Background

In this Chapter, a review of related work on forecasting better prices for trip packages based on historical sales data and related factors in the context of Europe Railway Tourism is discussed. Section 2.1 provides a brief introduction about Europe Railway Tourism and Flam Railway. Section 2.2 provides an introduction to price forecasting and trip price forecasting and section 2.3 discusses the existing approaches for price forecasting. Finally section 2.4 discusses the weaknesses in existing approaches for price forecasting.

Literature Review provides answers to the following Research Questions

- What are the current techniques for pattern recognition, business intelligence and forecasting better prices while also considering external factors?
- What are the gaps in the current techniques described in Research Q1 with respect to forecasting better prices based on sales patterns considering related factors in Europe railway tourism?

2.1 Introduction to Europe Railway Tourism and Flam Railway

Today travelling and tourism has become a rapidly increasing industry. It has become a major income method for some countries which have a lot of places with natural and historical importance. Because of that, the tourism industry has contributed to the local and also global economy massively. Tourism corporations have played a major role in this contribution to the tourism industry. Because of that there are a lot of tourism corporations which organise tours locally and globally with the help of information and Technology. Competition between these corporations to attract customers is that they are using a lot of offers, fascination packages etc. To gain the competitive advantage there is a trend to use machine learning and price recommending systems to offer most profitable offers to their customers.

2.1.1 Europe Railway Tourism

Europe is a major tourist attraction place in the world due to the significant, historic and attractive places. And also millions of tourist who love to experience variations of climates, weather, seasons and culture. Considering the shares of arrivals in 2017, Europe has the highest amount of shares recorded as 51% [1]. According to the statistics on 2017, there were more than 672 Million tourist arrivals have been recorded and it is an increment of +8% when considering the previous year [1]. Tourist industry has contributed to the economy of Europa Region by 519 Billion USD in 2017 and it was an increment of +8%. Considering the statistics on 2017, the most popular transportation mode among the tourist is by Air [1]. But considering the Purpose of visit, 55% of tourists have arrived in 2017 for leisure, recreations and holiday [1]. Due to that most of the tourists use air for the arrival to a country but for the inbound tourism most of them are using Railways as the transportation mode.

According to the NationalGeographic.com [2], Railway tourism has been promoted due to the facilities such dinning, comfortable and sleeper compartments. And also it an economical mode of transport with huge facilities. Due to the Tourism Railways are routed among most attractive tourists destinations, tourists are able to locate different site seen locations. According to NationalGeographic.com, the Top 10 Railway trips in Europe are listed below [2].

- Sweet Switzerland: The Chocolate Train
- Tunnels Galore: The Bernina Express
- A Hotel on Wheels: Trenhotel
- The Epic Journey: Trans-Siberian Railway
- Waterworld: The Flam Railway
- Bavarian Bullet: InterCity-Express (ICE)
- The Elegance of Yesteryear: Venice Simplon-Orient-Express
- Roughing it by Rail: Balkan Flexipass
- Luxury on Wheels: The Balkan Odyssey
- A Nostalgic Journey: El Transcantábrico Gran Lujo

2.1.2 VisitFlam and Flam Railway

VisitFlam

VisitFlam is the destination company for sales and marketing of the Flåm- and Aurland region on both national and international extent. Key elements in the company marketing are the brand Visit Flåm and through Internet portal www.visitflam.com. The vision behind Flåm AS is to create the world's best fjord destination and its mission is to provide and sell excellent sustainable experiences [22]. The VisitFlam is a group of companies that provide tourist facilities in different tourist attractive places in the Norwegian countries with different regions. And also they provide variation of what facilities to

their customers. there is awesome highlighting facilities and tourist destinations such as FLÅMSBANA - THE FLÅM RAILWAY, FLÅM AS, THE FJORDS DA, FRETHEIM HOTEL, FRETHEIM HOTEL and AURLANDSKOEN ÉCONOMUSÉE.

The railway is the major tourist attraction in the company that runs on daily all year round. . From Flåm by the shore of the Aurlandsfjord up to Myrdal station on the Bergen Railway, 866 meters above sea level. The purpose and vision behind Flåm Utvikling AS is to maintain and develop the Flåm Railway as one of Norway's major tourist attractions and develop Flåm and its surroundings into one of the prime tourist destinations in Scandinavia. Flåm AS and NSB – Norwegian State Railways, own the company 50 percent each [3].

Flam AS is the company that offers regular sightseeing tours, activities, accommodation and package tours by boat and bus in the Flåm and Sognefjord area. In addition, Flåm AS offers a wide range of package tours combining boat, train and coach as well as charter [3].

The company The Fjords DA offers regular sightseeing tours and charter between Flåm – Gudvangen, in other parts of the Sognefjord area, as well as between Geiranger – Hellesylt, Hjørundfjord, Oslofjord and on the Lys Fjord near Stavanger. Owners of The Fjords DA are Flåm AS and Fjord1 with 50 percent each [3].

The Flåm Railway Museum gives an insight into the building of one of the world's steepest railways, the technical development and the people behind this unique engineering work. The museum is open all year and offers free entrance.

The traditional Aurland Shoe is being produced in Aurland, at the only remaining shoe factory in Norway producing the traditional shoe.

Products and Services

Flam Group is conducting their sales of their products and services in four main regions in Norway. [4]

1. One entry in the list
2. Another entry in the list
3. Stavanger Region
4. Oslo Region

In Flåm Region there are some sub products and services conducted by the company [4].

1. The Flåm Railway
2. The Fjords Product
3. Fretheim Hotel
4. Flåm Area and Port

5. Attractions and activities in the Flåm area

In This research, it is only considering the product of the Flam railway service that was offered with the 50% combination of the Norwegian State Railway along the Aurlandsfjord.

- **The Fjords** Owned by Fjord 1 Flåm AS

- Boats on Geirangerfjord
- Boats on Lysefjord
- Boats on Nærøyfjord
- Boats on Sognefjord
- Boat on Hjørundfjord

Flam Railway

Flam railways is one of the few private railways that has decided to offer the journey from Flam to Myrdal which is situated 876 metres from the sea level along the UNESCO heritage Fjord valley. The journey is decided to Flam to Myrdal, which is owned by the Norwegian State Railway. The distance of the journey is 20 km and its 80 percent of the track has 5.5 percent of gradient and its smallest curve is 130 metres.

According to their reports [3], the Flam Railway 1435 gauge railway tracks as the railroad is located with a narrow route. The main power train of the rail is electric powered locomotive after the Norwegian State Railway has converted their locomotives as electric locomotives in 1944 [5]. The power stations situated in the suburb area which are driven by the waterfall generate electricity of the drive trains by empowering the “Green” concept in the UNESCO heritage region. According to the report, Flam is going to implement a fully electric vessels for the cruising in other products by converting the boats into electrified propellers[3].

In regular trains there are two electric locomotive engines which are powered by the 15000V of grid connection [6] which weighs over 64 tons each (According to the reports, the secondary break engine of the locomotives provide electricity for the national grid by dynamic braking [5]) . There are six carriages with 525 seats weighing 40 tons without passengers and 45 tons with passengers. Overall train is more than 182 metres in length with 6 carriages and 2 engines. Trains are transported according to the published time table from Flam - Myrdal - Flam. Number of train turns will be varied according to the passengers and according to seasonal changes.

Facilities and Features

The Flam Railway provides group or individual bookings for the selected destination will it return tickets one-way tickets. And also the trains are equipped with cycle carriages and also special facilities for the disabled people. The train fare will be varied according to the age groups such as it can be varied for the elders and for children.

Departure and Destination

Flam Railway started from the city of Flam which is 2 meters from the sea level. Its final destination is the city of Myrdal which is 865 meters above sea level Along 20 km. This journey grew through eight Railway stations, 20 tunnels and 4 water tunnels [2]. The maximum speed of upwards is 40 kilometres per hour and downward maximum speed is what I would do to the huge descent. Along with this Railway track. So many beautiful places such as mountains, waterfalls, historical places and also site scenes. To be slower, visitors are able to observe the environment and sometimes trains will be stopped or slowed down near some specified places. For the return tickets visitors are able to travel Myrdal and return to the Flam again. One way tickets I am able to go to the specified destination and travel to be the package such as Train hiking, cycling, boat travel, hotels or for the ancient places.

Bookings and Seat reservations

The booking for the tickets can be done by online store of the flam railway or using the authorized ticket outlets from the Norwegian State Railway (NSB). Or It can be done by the authorized third-party agents such as online Citybreak Agent Network, - or on the spot in premises in Flåm Visitor Centre Train Station. There is a total capacity of 525 seats divided into six carriages. Companies are recommended to reserve seats in advance because there will be some fully booked dates frequently. Users are able to book their seats by groups or as individuals. If the seats are booked they are marked as reserved and if there is a name for the group it will also be displayed. If the visitor is an individual person it is able to reserve seats as individuals and if the carriages are full, there will be an additional carriage for individual visitors. If the group of the visitors require different language for guidance, the LCD screens are displayed by their preferred language. Tickets can be booked using the age group or the type of the package that the user selects. For the cancellation of the ticket, it is able to contact the agent or directly to the company for the mutual cancellations.

Business and Information Terminals

VisitFlam's main terminal for attracting customers and place orders is their online website www.visitflam.com. In this website they have included their destinations tourism packages and their timetable and also charges for each and every package [1].

According to the report, there are some agents, who can provide tickets and packages to the customer on behalf of VisitFlam. Their agent is Norwegian State Railway (NSB) conduct rate tourism packages with Cooperatively them [3].

According to the figure they have predefined charges for the tourism packages for the railway for 2020 [3]. There are tickets called One Way Ticket and also return tickets which allow customers to select their packages and destinations.

There are so many train turns in the year. But according to the weather and their past experience they have free define the number of train tours for some seasons.

Flåm Myrdal or Myrdal–Flåm (One way) – Flåm–Myrdal–Flåm (Return)			
01 January-30 April		One way	Return
Ordinary adult ticket		NOK 360	NOK 490
Ordinary child ticket 6-17 years		NOK 180	NOK 244
01 May-30 September		One way	Return
Ordinary adult ticket		NOK 430	NOK 630
Ordinary child ticket 6-17 years		NOK 215	NOK 314
01 October-31 December		One way	Return
Ordinary adult ticket		NOK 370	NOK 500
Ordinary child ticket 6-17 years		NOK 185	NOK 250

Figure 2.1: Proposed prices for Flam Railway 2020

2.2 Introduction to Price Forecasting and Trip Price Forecasting

Price Forecasting has become very crucial as nowadays as customers seek to get a lower price while companies try to keep their revenue as high as possible and maximize their profit. Therefore it is becoming very much essential to use various computational techniques to increase the company's revenue such as demand prediction and price discrimination[7]. Similarly Trip price forecasting is used to determine a best price for the trips that the company provides to their customers while considering also the external factors that affect the trip price using the computational techniques.

One of the key issues from a customer point of view is determining the minimum price or the best time to buy a ticket. The concept that tickets bought in advance are cheaper is no longer working[8]. It is indeed possible that customers who bought a ticket earlier than others pay more than those who buy a ticket later. It is also true that early purchasing implies a risk of commitment to a certain schedule[9]. Early booking will not see the weather and seasonal changes which will happen later. Therefore it is clear that trip ticket price may be affected by several factors and thus the trip price may change continuously.

Many companies of the tourism industry are now intensively using data analysis and sophisticated mathematical techniques to predict the willingness of various customer segments to pay and also to maximize their profits. This has naturally resulted in a price discrimination phenomenon which depicts that the same service which can be same category of seat for a trip being transacted at different prices. This fluctuation of prices is a worry for the customers. Therefore it becomes very difficult for the customers to decide to buy a ticket or not to a certain price in a certain time. This also naturally opens the way for supply of possibly new services which could be used as decision making tools for customers[10].

Therefore various price forecasting techniques are used to predict the price of a trip which could be good from both the customer and the trip offering companies points of views. According to Aggarwall et.al[11], it is seen that according to the nature of the model price forecasting techniques can be categorized as below.

1. Heuristic models
2. Simulation models
3. Statistical models

Below also shows the diagrammatically the approaches which could be used based on the above models[11] (Figure 2.2).

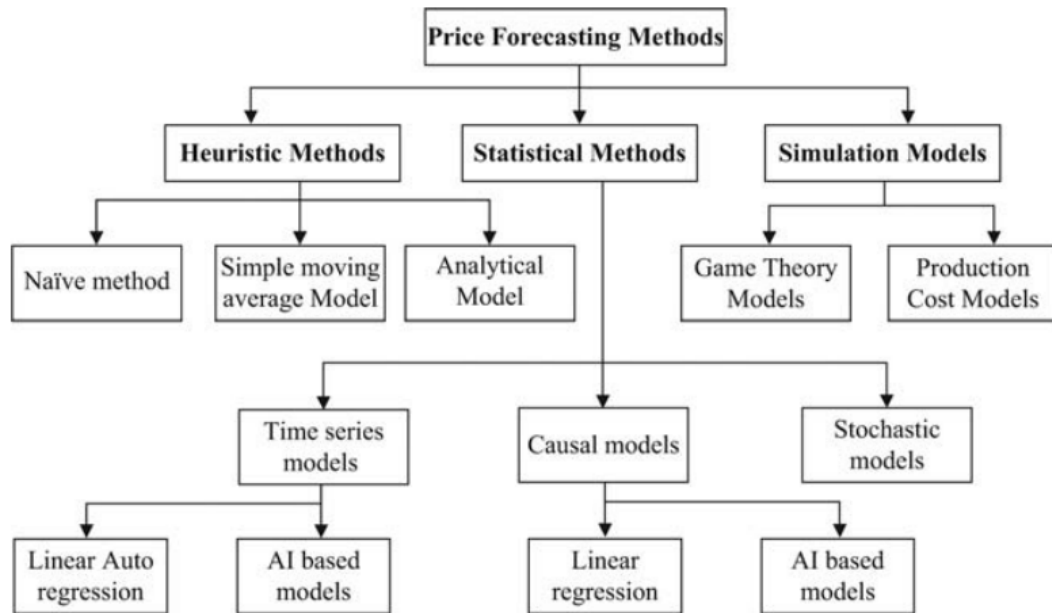

Figure 2.2: Price Prediction Model

2.3 Existing Approaches for Price Forecasting

Price Forecasting has been done using various approaches and even some have done using more than one method. Price Forecasting Approaches are very much essential in identifying the approaches to be used for the trip price forecasting.

According to Makkonen et.al [12], electronic commerce especially in the business-to-consumer context has become very popular. Therefore they have identified the most typical sales patterns of online stores in the B2C context. They have segmented the monthly sales time series of 399 online stores with time series clustering. They were able to identify four approximately equalled sized segments of which two were characterized by a clear upward or downward trend in sales and two were characterized by strong seasonal variation. They also got this result by exploring 14 business and technical parameters which includes Monthly sales, item categories, payment methods, customers, campaigns etc. Therefore from this it is very clear that analysis of sales data could be done using time series and variations of prices could be seen based on different external factors such as seasons.

As our dataset contains seasonal and time series we need a model which supports variations in seasons and which can be used to see the seasonal trend. According to Permanasari et.al [13], due to the seasonal trend in time series the Seasonal ARIMA can be selected as the model to be used. Here they have forecasted the number of malaria incidence by using the time series model SARIMA. They have used Mean Absolute Percentage Error (MAPE) in measuring the error percentage or the accuracy of the SARIMA model. Similarly SARIMA model could be used to forecast the price.

In our research we consider only 3 external factors in predicting trip prices which are

weather, season and holidays. According to Arunraj et.al [14], the daily demand for fresh food products is affected by external factors such as seasonality, price reductions and holidays. They have divided holidays into 4 categories as regular holidays, Christmas, Easter and school vacations. The two types of price reductions they have used are discount price reduction and promotional price reduction. The seasonality they have taken is according to weeks and as on sundays the retail shops in Germany are closed they have taken the seasonal length as 6 considering from monday to saturday. This represents the sales pattern in a week. Then they developed a Seasonal Autoregressive Integrated Moving Average with external variables (SARIMAX) model which accounts for all the above external factors to forecast the daily sales considering also the demand. It was found that the proposed SARIMAX model improves the traditional Seasonal Autoregressive Integrated Moving Average (SARIMA) model and is very successful. Therefore from these facts we can conclude that SARIMAX model can be used in our research.

Two external factors we are considering when considering a better price for a trip are holidays and the weather. According to Chen et.al [15], temporal factors they have selected are months, weekdays and holidays and the weather forecasts which were selected as predictive factors were daily mean temperature, amount of rainfall and the amount of snowfall. Accordingly they used seasonal auto-regressive integrated moving average model with external regressors (SARIMAX) as they used the above temporal factors and predictive factors as external factors. A series of SARIMAX models of different orders was estimated and diagnosed. A general linear model (GLM) was also developed and was compared with the SARIMAX models by validity measures. They concluded from evidence of model validations that both SARIMAX and General Linear Model (GLM) can be used in forecasting daily collisions. Similarly trip prices also could be forecasted. General Linear model cannot be used in our research as it is used when there are more than one dependant variables but we have only one dependent variable which is the price.

One of the statistical methods which could be used for price prediction is linear regression. According to Tudy et.al [16], predicting daily behavior of a stock market is a serious challenge for corporate stakeholders and investors and could help them to invest more confidently by taking into consideration the risks and fluctuations. Therefore to prove that stakeholders can confidently invest prediction of SP 500 index was done by using linear regression. To do linear regression they had first divided the dataset as training and testing. It was able to obtain the coefficients, slope, error and the intercept by applying the linear regression model. Through this they were successful in proving that a good performance can be seen by applying the linear regression model. Here the linear regression method is done is Multiple Linear Regression Method. Multiple Linear Regression is also called Multiple Regression. Multiple linear regression which is considered a statistical technique uses several explanatory variables to predict the outcome of a single response variable.

According to Shinde et.al [17], for predictions of the sales price of houses various machine learning algorithms could be used. Housing sales prices are normally determined considering numerous factors such as the location of the house, area of the property, material used for construction, number of bedrooms, age of the property, and garages etc. Here they have used decision trees, Logistic Regression and Support Vector machines.

They have considered housing data of 3000 properties. Here from Logistic Regression and SVM R-squared values of 0.96 and 0.81 were obtained showing that both models show good performance. This was further proved by the comparisons of the algorithms based on parameters such as Mean Absolute Error (MAE), Mean Square Error (MSE) and Root Mean Square Error (RMSE). Logistic Regression cannot be used to our research as our dependent variable price is not binary in nature but linear regression can be used as price is continuous and regression is linear. From these facts it is clear that for our research linear regression could be used in price forecasting. According to our dataset multiple regression is the most suitable one as we have more than one independent variable. Support Vector machine is also an option to be considered.

Linear Regression can be done using several methods. One of the methods is Multiple linear regression which is discussed above and one approach of Multiple Linear Regression which can be used is Ordinary Least Squares method and it is the most commonly used multiple linear regression method. According to Lin et.al[18], Ordinary least-squares (OLS) regression is emphasized as a generalized linear modeling technique that could be used to model a single response variable, which has been recorded on at least an interval scale. The technique may be applied to single or multiple explanatory variables and also categorical explanatory variables that have been appropriately coded. As we have weather, season and holidays as explanatory variables this method is considered suitable.

According to Dubin et.al[19], the ordinary least squares (OLS) linear regression is the standard method used to build hedonic price models. Also it is shown that ANN algorithm used in the study was outperformed by ordinary least squares (OLS) regression. Therefore ordinary least squares model is certainly an option we should try and use in our research.

P. Pai et al has compared Seasonal Support Vector Regression models with Autoregressive Integrated Moving Average and Support Vector Regression models and has concluded that the SSVR is much better at predicting time series data [20].

Z. Sun et al have proposed an artificial neural network [ANN] learning algorithm called Extreme Learning Machine (ELM) for sales forecasting in the fashion retailing industry. This is a single-hidden-layer feedforward neural network where the input weights and hidden biases are randomly chosen and the output weights are analytically determined by using the Moore–Penrose (MP) generalized inverse. [21] Artificial neural networks and support vector machines are used extensively forecasting time series data.

P. Chang and Y. Wang states that the most rewarding method for sales forecasting is integrating artificial neural networks with fuzzy theory. They have used the Step wise Regression Analysis and Fuzzy Delphi Method to filter the key variables to be analyzed. They have concluded that the Fuzzy Back Propagation Network is performing significantly better than Grey Forecasting, Multiple Regression Analysis and traditional Back Propagation Network[22]. This shows that Artificial Neural Networks perform well.

R. Kuo and K. Xue also have used a Fuzzy Delphi method in creating a forecasting system which can handle external factors such as promotions. [23]

2.4 Weaknesses in Existing approaches for Price Forecasting

According to M.Makkonen et.al [12], prediction from a time series can only be done for the time period of the dataset. That is we can divide the dataset as training and testing and can predict for the testing dataset but we cannot predict for another dataset. If we want to predict a pattern for future data, then data needs to be there till that date to predict the pattern. Therefore the weakness in time series or SARIMAX is that continuous data is needed for prediction and also can only predict for the time period of the dataset.

According to Shinde et.al[17], they have concluded that decision trees overfit although they get a 100 percent accuracy in predicting house prices. They also say that doing house price prediction using decision trees is a problem because decision trees take into consideration the noises that are present around. Although they have tried to divide the dataset for training and testing as 50:50 they have not succeeded in solving the overfitting problem. Therefore because of overfitting in decision trees in price prediction we are not using decision trees.

According to Z. Sun et al[21], over tuning and high log computation time is inherited problems in using Extreme Learning Machine. Over tuning of parameters results in the model not being accurate. Although Extreme Learning Machine is fast it is not very accurate because of the over tuning. Also another weakness of Extreme Learning Machine model is that it has a high log computational time. This is because of the higher complexity. Therefore we did not take the Extreme Learning Machine for the final hybrid model.

According to Palmer et.al[24], one of the weaknesses of linear regression is that it provides only a linear relationship. Also linear regression has a weakness of correlation measures in providing diagnostic. Because only providing linear relationships linear regression or Normal Linear Regression can only be used in scenarios which require linear relationships. Also another weakness is that Linear regression is sensitive to outliers. Therefore it is wise not to use linear regression if there are many outliers.

According to Wang et.al[25], In Support Vector Machine(SVM) numerical optimization in a high-dimensional space may suffer from the curse of dimensionality. This will result in obtaining a non optimal solution. As it is dealing with numeric data it is not wise to implement SVM if there is a higher-dimensional space. Weather, season data and price are numerical so we should be cautious when implementing SVM.

H. Cao et al propose a support vector regression trained by particle swarm optimization to predict warrant prices. "A Support vector regression (SVR) technique is a learning procedure based on statistical learning theory, which employs structured risk minimization principle." The accuracy of the SVM depends on the training parameters. H. Cao et al have used particle swarm optimization when selecting the training parameters and applied it to warrant price prediction [26].

According to the Murat et al. (2016), The price of the tourism products will depend on internal and external factors. The internal factors are marketing cost structure and cost decision mechanism. The external factors of market structure, product price of oppo-

nents, chain of distribution in legal legislations. Most of the tourist companies determine their prices by analyzing various factors suggesting market structure and conditions of competition. The suppliers choose a pricing structure which allows them to share their products on the online channels and they have three very important results with the help of Van Westendorp PSM method. These are Optimal price point, Acceptable price point, and Indifference price point. There are some factors that affect the pricing of the tourism industry. They are cost, competition, judicial factors, demand in the market structure, factors depending on distribution channels and consumer behavior [24].

According to our research we mainly consider the external factors weather, season and holidays. The pricing structure is organized according to the different trip packages. Also, in order to give a better price, we are considering an Acceptable price point. But we don't have the cost for trips. It is not possible to calculate profit using our models and a gap is that different models use different data formats in processing based on the factors used.

Chapter 3

Methodology and Design

3.1 Introduction

3.1.1 Research Purpose

This chapter elaborates on the design of the research where researchers strive to compare the price predicting models to circumvent the inherent weaknesses in the traditional methods in recommending and predicting a price.

This study uses Railway Tourism data provided by the Flam Railway of the Visit Group, Norway obtained via collaboration between Creative Software and the University of Colombo School of computing and selected external factors related to the tourism industry.

3.2 Research Questions

- **Research Q1:** What are the current techniques for pattern recognition, business intelligence, and forecasting better prices?
- **Research Q2:** What are the gaps in the current techniques described in Research Q1 with respect to forecasting better prices based on sales patterns considering related factors in Europe railway tourism?
- **Research Q3:** How to propose a better price model to forecast prices based on sales patterns to the Europe railway tourism to overcome gaps in Research Q2 by considering the other factors?

3.3 Research Design

This research strives to implement the most popular price forecasting models and evaluate and compare those models to find the weaknesses in each of them. Then the researchers will implement a hybrid model to mitigate the impact of these weaknesses to the forecasted price. Research design (Figure 3.1) highlights the main 11 steps researchers are following to get the expected results.

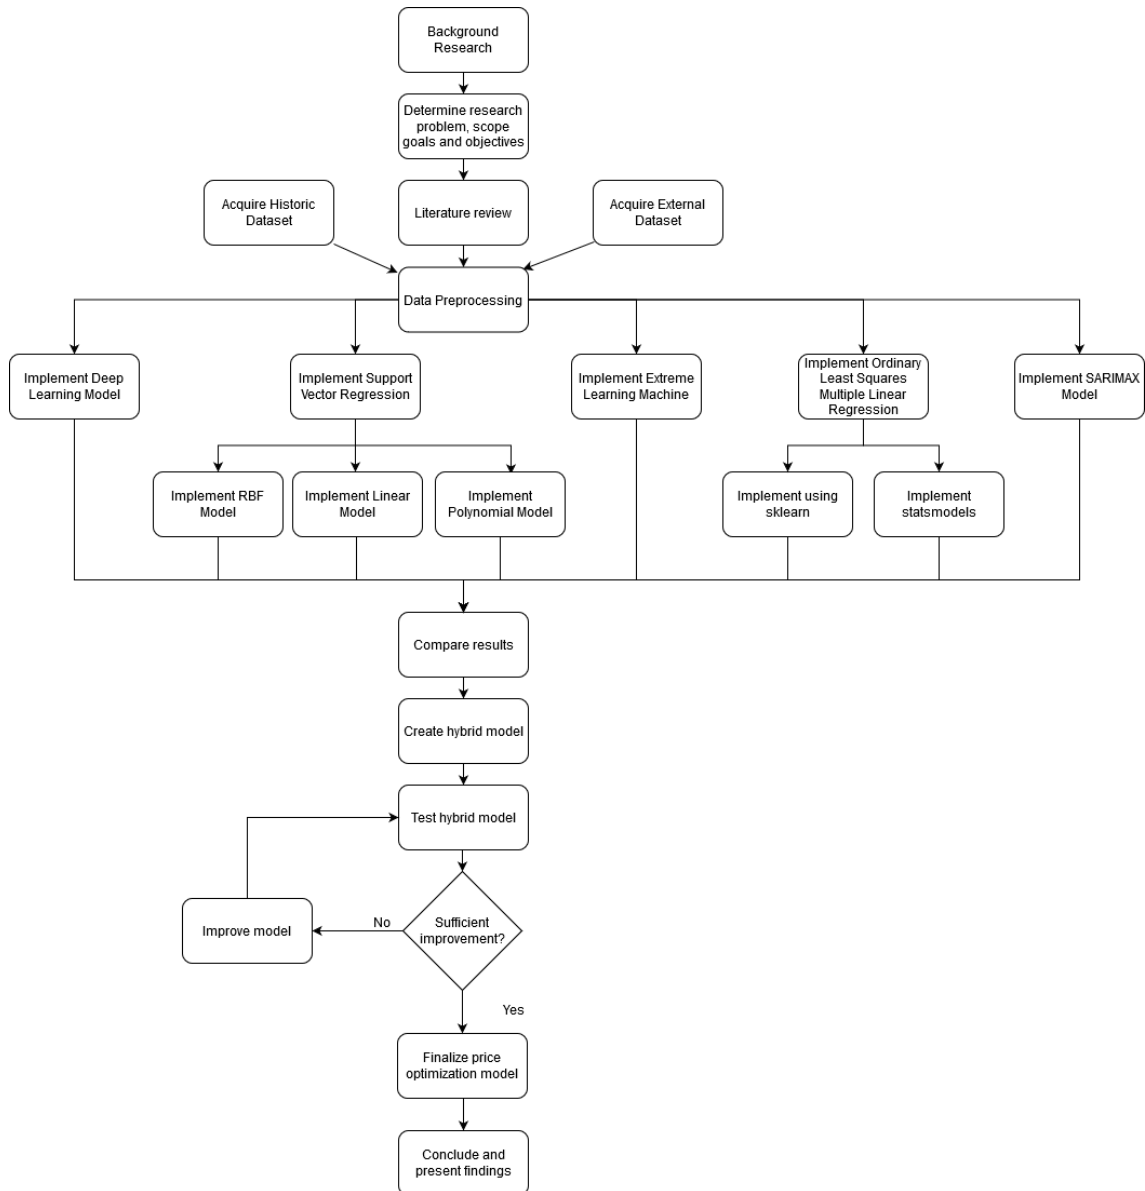

Figure 3.1: Research Design

3.4 Methodology

Initially, data was provided by the Visit Flam with related tables for all trips handled from 2008 to 2019. Due General Data Protection Regulations, the personal and identical data of the customers are not provided and set as null values in the database. Data for the train tours are filtered with relevant tables. Each and every trip has obtained its own TripId by automated Online Reservation System. According to the package that the customer chose, Trip Legs are created. Trip Leg is a single arrival and departure between two destinations (two railway stations) and a trip should be obtained at least one Trip Leg. By considering the sequence of arrivals and departures, every Trip Legs were concatenated according to Trip ID to create a unique trip based on the Trip Package. There are 89 identical trip packages and 3 of them are return trips. The base fee for the trip package for a certain day is considered as the Price for that Trip package on that day. The acquired location based weather data, holidays and Seasons are joined to the trip

data set and analyzed by the methodologies mentioned below.

3.4.1 Background Research

A background study on recommender systems, business intelligence, price forecasting, and railway tourism was done by the researchers to gain a high-level understanding of the problem domain.

3.4.2 Determine the research problem, scope, goals, and objectives

After the background research problem, scope, goals, and objectives were decided as mentioned in the introduction.

3.4.3 Literature Review

A literature review was done to get a comprehensive understanding of current solutions to forecast a better price as discussed in the related work.

3.4.4 Acquire historic data

Dataset for the research was provided by client company with the data of the other packages and tourism activities. The provided data set has trip records from 2008 to 2018 with over 3.1 Million Trip records.

3.4.5 Acquire external data

External data was acquired using two online APIs. Weather and seasonal data were obtained through the World Weather Online API [27]. Holidays data was obtained through Time and Data API [28].

3.4.6 Data preprocessing

Data preprocessing was done using the Microsoft SQL server management studio 2017. Data was obtained as a BACPAC file which was then imported to SQL server management studio. Then according to the product flam railway of Visit Flam 7 tables were selected and the data set was created by joining them using certain conditions. Then the external data of weather, season and holidays which was collected was joined with the dataset created by joining the seven tables. In data preprocessing mainly rows which are null and also repeating rows were avoided. Furthermore, data that was identified as test data was removed.

The trip was considered as the selling product and trip packages were identified as the factor to which price has to be forecasted. Trip packages are built by the combination of departure legs. Trips go on different days through the same locations belong to one trip package. After preprocessing 89 trip packages were identified with 3,166,844 rows of trips.

Below shows the final query and results in the Microsoft SQL server management studio by joining all other data with the weather table. These preprocessing was done

considering that Instance Id 24 is Flam Railway product of Visit Flam and PriceGroup Id 92 is Adults for which only we predict prices.

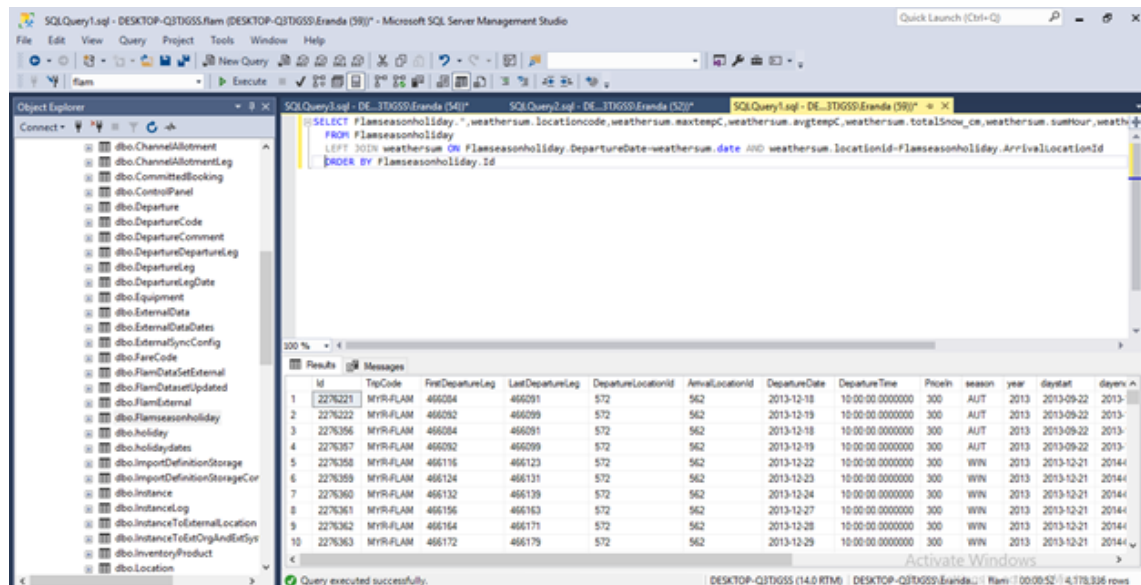

Figure 3.2: Sample Data Set

Trip Package Creating

The Trips of the Flam Railway is based on the railroads across eleven stations around the site seen areas. Tourists are able to join to the train trip at any station and end the train trip at any station and join for the other kind of sightseeing tours such as boat rides and hotels. By considering the patterns and the frequency of the usage of the arrival and departure stations of the tourists, Flam Railway has been designed pre-defined train packages that cover all the significant stations. For example, if a tourist reserved a trip from the Station A along the Station B and C to Station D, it is identified as a unique trip package. In Flam Railway, there are 89 distinct trip packages including one way and return trips. In the system, the locations/Stations are identified using its unique code

In the automated reservation system, train trips are recorded in two tables.

- Trips
- Trip Legs

Trips are the unique reserved trips that included the above unique trip packages. For example, if a tourist reserved a trip from the Station A along the Station B and C to Station D package it was identified as a trip from A to D.

The 'Trip' table, which contains the following details in the record row.

- **TripID** - Unique ID for the Trip
- **First Departure Location** - Initial departure location of the Trip
- **Last Arrival Location** - Trip's Final Destination
- **Trip Code** - Indicate the First Departure and Last Arrival Stations (For example, if the Trip is Scheduled from Station A to Station B, It was Recorded 'A - B ' as the trip Code

- **Departure Time** - Departure time and the date of the trip from the first Departure Location according to the train schedule
- **Arrival Time** - Arrival time and the date of the trip to the Last Arrival Location according to the train schedule
- **PriceIn** - Price for the Trip

Trip Legs are the departures and arrivals between the intermediate stops for the unique trip with its package. For the train ride, trains have been allocated from the main departures and destinations frequently. The number of trains and their schedules is predefined by the company according to the fast experience. The train will stop at each station along the train route.

For example, if the tourist reserves a trip from Station 'A' to 'D' along the B and C stations, the train ride between A to B is considered as a Trip Leg. Simply the train will depart at Station A on the scheduled time and arrive at Station B. For the above-considered trip, there are three Trip Legs that can be identified as a Trip Leg. Then it departs from Station B and arrives at Station C. It can be considered as another TripLeg. Then It departs from station C and arrives at the station D. It is the last TripLeg for the package. Then the tourist will go to the destination.

Considering the above trip A-D is the trip code for the trip, the trip package plans to cover 4 stations. The trip has three Trip Legs such as A to B, B to C and C to D. and also these trips have two intermediate stops such as B and C station.

Every trip includes records for the number of TripLegs including the following details

- **ID** - Unique id for the TripLeg
- **TripId** - Unique Trip Id that trip leg belong to
- **First Departure Location** - First Departure Location of the considered trip
- **Last Departure Location** - Last Departure Location of the considered Trip
- **Departure Location** - Departure Station of the TripLeg for the considered Trip
- **Arrival Location** - Arrival station of the Trip Leg for the considered Trip
- **Departure time** - Departure date and time of the departure station according to the Train schedule
- **Arrival time** - Arrival date and time of the arrival station according to the Train Schedule

To determine the trip packages of the Flam Railway, the following steps were executed

- Determine the Unique TripIds and First Departure Location from the 'Trip' table.
- Select the TripLeg which are included in each and every TripId.
- Sort the TripLegs according to the ascending order of the Departure time.

- Concatenate the First Departure Location with Sorted Arrival Locations with the '>' symbol.
- Created Trip Package was Appended to the particular TripID Record.

Example Scenario

Consider the Trip which has 1 for the TripId which Departs from Station A at 20/10/2019 09:00:00 along Station B and Station C to arrive at Station D at 20/10/2019 10:00:00 [Table 3.1]

TripID	First Dep. Locat.	Last Arrival Locat.	Trip Code	Depa. Time	Arrival Time	PriceIn (USD)
1	A	D	A-D	20/10/2019 09:00:00	20/10/2019 10:00:00	100

Table 3.1: Sample Trip Data

Then all the TripLegs are selected and sorted according to the Departure Time. [Table 3.2]

ID	TripID	First Dep. Locat.	Last Arrival Locat.	Dep. Locat.	Arrival Locat.	Dep. Time	Arrival Time
1	1	A	D	A	B	20/10/2019 09:00:00	20/10/2019 09:20:00
2	1	A	D	B	C	20/10/2019 09:20:00	20/10/2019 09:40:00
3	1	A	D	C	D	20/10/2019 09:40:00	20/10/2019 10:00:00

Table 3.2: Sample TripLeg Data

Then the First Departure Location and Arrival Location of the Sorted TripLegs were concatenated with > symbol

A > B > C > D

Created Package was appended to the considered Trip.

TripID	First Dep. Locat.	Last Arrival Locat.	Trip Code.	Dep. Time	Arrival Time	Price IN	Package
1	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	100	A > B > C > D

Table 3.3: Sample Trip Data with Trip Packages

By considering the above scenario 89 Unique Trip Packages were identified

Trip Price Identification Flam Railway Trip Packages provides facilities such as meals, beverages and bike rides for the tourist. If the tourists consume these facilities within the train rides, they have included the charges for those facilities for the price of the train ticket. As the facilities can be noise for the data set, it is needed to remove those additional charges from the train ticket. As the base price of the train ticket has not been provided due to the company policies, under the guidance of the Flam Railway, the Base Price for the train rides was assumed under the following assumption.

Assumptions

1. At least one trip has been recorded for the particular day and particular packages with the base price of the trip package without any additional charges.
2. The minimum price should be considered as the base price of all the trips of the considered day and considered package.

Base Price Identification

To assign the base price of the trip package for the particular date, the below steps are followed.

1. Select a trip package
2. Select a single day for the selected trip package.
3. Select all the trips for the selected day and trip package.
4. Identify the minimum price from selected trips
5. Assign the minimum price for all the selected trips.

Example Scenario

TripID	First Dep. Locat.	Last Arrival Locat.	Trip Code.	Dep. Time	Arrival Time	Price IN	Package
1	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	100	A > B > C > D
2	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	120	A > B > C > D
3	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	110	A > B > C > D

Table 3.4: Sample Trip Data

By following the above steps, base trip prices can be determined as the table given below.

TripID	First Dep. Locat.	Last Arrival Locat.	Trip Code.	Dep. Time	Arrival Time	Price IN	Package
1	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	100	A > B > C > D
2	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	100	A > B > C > D
3	A	D	A-D	20/10/19 09:00:00	20/10/19 10:00:00	100	A > B > C > D

Table 3.5: Sample Updated Trip Data

3.4.7 Implementing Models

Implementing machine learning models

In this step following models that are determined as most successful to determine a better price will be implemented.

- Deep Learning Model
- Support Vector Regression
 - RBF Model
 - Linear Model
 - Polynomial Model
- Extreme Learning Machine

Implementing statistical models

In these steps following statistical models are used in determining a better price with greater accuracy.

- Ordinary Least Squares Multiple Linear Regression
 - Using sklearn
 - Using statsmodels
- Seasonal ARIMA model with Exogenous Variables (SARIMAX)

3.4.8 Comparing results

Each model which was implemented was tested for the accuracy of price prediction. Results of the testing can be found in the Chapter 4 Results and Evaluation. The model that has the lowest root mean square error was considered the best in predicting the price for each package.

Deep Neural Network

Deep Neural Network was implemented using Tensorflow and Keras using Python language. In the first phase a classification deep neural network was created with 183 input nodes, 256, 128, 64, 32, 16, 8, 16, 32, 64 nodes in 1st to 9th hidden layers and 120 output nodes. This model was able to predict the price with 21.74% validation accuracy.

In the second phase a regression single layer neural network was created with the intention of assessing the effect of number of nodes in the layer on the accuracy of prediction. Neural Network was trained for number of nodes from 1 to 340 and the testing was abandoned as the researchers couldn't find any significant relationship between number of nodes and the prediction accuracy. Pearson correlation coefficient for the above relationship was -0.13738 which suggests there is no correlation between number of nodes and the prediction accuracy and validates the researchers' observation. Maximum validation accuracy gained by this model was 10.0128%. Following Accuracy vs Nodes graph shows all the observations gathered by the researchers (Figure 3.3).

Figure 3.3: Accuracy vs Nodes for Neural Network

After that it was determined that there are too many redundant variables in the dataset. Correlation matrix of the numeric variables are as follows (Figure 3.4).

Figure 3.4: Correlation Matrix for Numeric Features

Next version of the Deep Neural Network used Standard Scalar to scale each attribute such that the mean is 0 and standard deviation is 1. It had 11 nodes in the input layers and 1024, 512, 256 nodes in hidden layers and 1 node in the output layer. A dropout layer of 0.2 was used between each hidden layer.

Unlike in the previous case instead of the whole dataset, model was trained for each package as it was determined to have much less root mean square error compared with using whole dataset.

Ordinary Least Squares Multiple Linear Regression (sklearn)

Linear regression model used here is a multiple linear regression model. Multiple linear regression was used because we have more than one explanatory variable to forecast the trip package price. In order to build the Ordinary Least Squares Multiple Linear Regression model the main library used here is sklearn. sklearn and statsmodels are the most popular libraries used in doing multiple linear regression. Other libraries used are pandas and numpy libraries were used and was written using python. In Ordinary Squares Multiple Linear Regression in sklearn, it fits a linear model with coefficients $w = (w_1, \dots, w_p)$ to minimize the residual sum of squares between the observed targets in the dataset and the targets which are predicted by the linear approximation[29].

The dataset was split for training and testing as testing dataset size being 20% and the training dataset size being 80% of the whole dataset respectively. To predict the price explanatory variables can also be given sample values as shown below and then by using Ordinary Least Squares Multiple Linear Regression model a price is predicted.

```
# prediction with sklearn
New_PackageNo = 83
New_Intermediate_stops = 0
New_DepartureDay = 1
New_DepartureMonth = 1
New_DepartureYear = 2018
New_SeasonNo = 4
New_isHoliday = 0
New_avgtempC = 4
New_sunHour = 1.5
New_totalSnow_cm = 0
New_uvIndex = 1

print ('Predicted Trip Price: \n', regr.predict([[New_PackageNo ,New_Intermediate_stops,New
```

Figure 3.5: Manual Price Prediction

Ordinary Least Squares Multiple Linear Regression (statsmodels)

In statistics, ordinary least squares (OLS) is a type of linear least squares method for estimating the unknown parameters in a linear regression model. Under the additional assumption that the errors are normally distributed, OLS is the least squares estimator. Under the additional assumption that the errors are normally distributed, OLS could also be the maximum likelihood estimator. Thereby Ordinary Least Squares model can be considered as a method of Linear Regression Model.

Ordinary Least Squares model is also called OLS model. Unlike sklearn, statsmodels library doesn't automatically fit a constant. Therefore it is needed to use the method `sm.add_constant(X)` in order to add a constant. Adding a constant while it is not necessary will make the line fit much better [30]. Other than sklearn statsmodels is the most popular linear regression library and it uses `sm` from statsmodels library for prediction as shown below. (Figure 3.6).

```
# OLS model
model = sm.OLS(Y, X).fit()
predictions = model.predict(X) # make the predictions by the model

print(Y)
print(predictions)

# Print out the statistics
print_model = model.summary()
print(print_model)
```

Figure 3.6: OLS Model

SARIMAX Model (Time series model)

The Time series model chosen was the SARIMAX model because the forecasting of trip package prices need to be done by considering season and trend details.

In order to build the SARIMAX model matplotlib, pandas, numpy and seaborn libraries were used and were written using python.

Similar to the linear regression model, training and testing sizes were split as 80% and 20% of the whole dataset. Also the data was scaled in order to get a more accurate result. SARIMA model with exogenous variables (SARIMAX) was used as we forecast the

price based on weather, season and holiday factors which need to be input as exogenous variables to get a better price[31].

Today's Trip package price is predicted by considering weather, season and holiday data of today and the manual price given by Flam railway. This is how the time series model works. The trip package 'BER->BLO' below shows how the season, trend, trip package of the next day and the correlation changes.

Figure 3.7: Trends of the Data Set

Figure 3.8: Trip Prices with Years

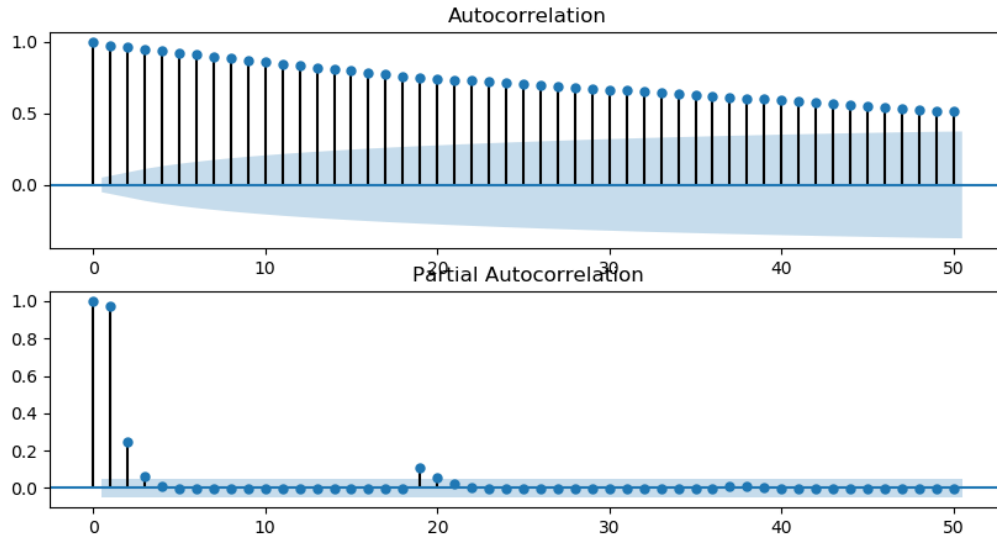

Figure 3.9: Correlation

Time series frequency chosen was daily as we have details for a trip package daily with the daily prices assigned for the trip packages. But we cannot use SARIMAX model to predict for the future dates outside the dataset.

Support Vector Regression (SVR)

Support Vector Regression can be used to predict the prices by analyzing the pattern of the impact from the external parameters. The data set is separated according to every package acquire better results. By training the data set by separately, it is planned to identify the error of the predicted price from selected parameter. According to the Correlation Matrix on figure, it can be assumed that the Temperature is the most correlated factor for the price (due to the intermediate stops are unique can constant for the Trip Package, it is not considered as a factor for the single package). Rather than temperature, Sun hour, Uv Index and snowfall is also trained to predict the prices. The prediction of prices are done by three sub models.

1. RBF Model
2. Linear Model
3. Polynomial Model

Extreme Learning Machine (ELM)

When the data set was analyzed by the extreme learning Machine (ELM), It takes only significantly less amount of time rather than the other machine learning algorithms because of the slow learning speed of feedforward neural networks due to the slow gradient-based learning algorithm and all the parameters of the learning algorithm are tuned iteratively. To avoid the bottlenecks ELM uses Single Hidden Layer Feedforward Neural Networks (SLFN) to analyze a huge amount of data set. It will be suitable for the research and for the domain as the data set is around 3.1 Million rows. Rather than other

Model, ELM can use to predict the Price Class (Suitable Existing Price) by considering the External Factors.

3.4.9 Create Hybrid Model

Hybrid model was created by combining Deep Learning Model and Ordinary Least Square Model to predict prices and a Linear Interpolation function with deflated price and sales volume to find the better price. Workflow of predicting a better price is shown in the Figure 3.10.

Reason for not using the SARIMAX model even though it showed the least error will be discussed in the Chapter 5 Discussion.

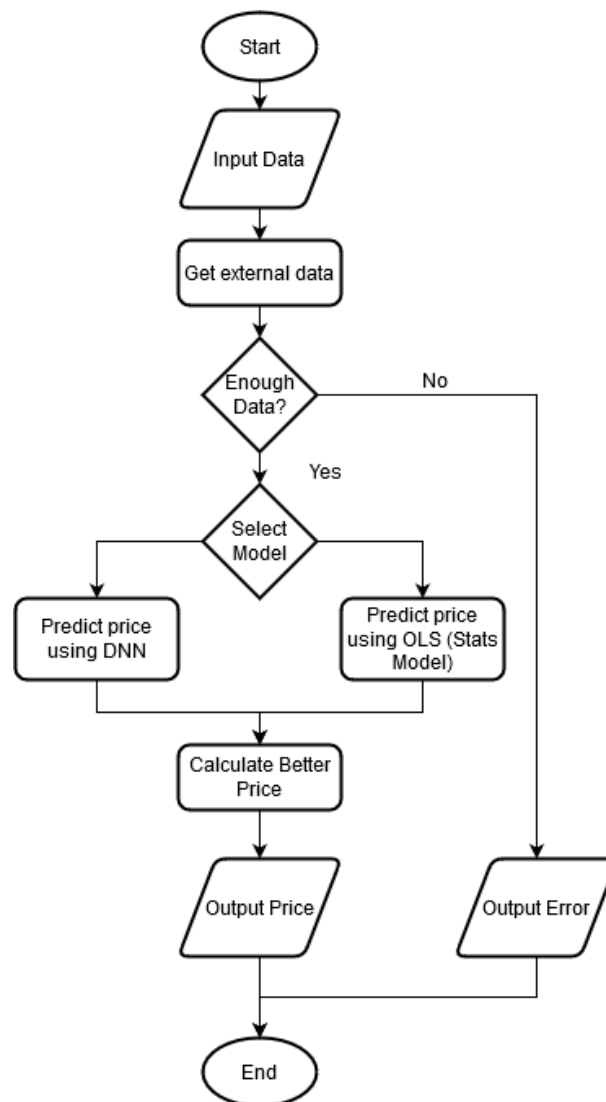

Figure 3.10: Better Price Prediction Workflow with Hybrid Model

Hybrid model consists of 2 parts. First part predict the current manual price use by Flam railway and second part calculate a better price.

Predicting Price

In this part the hybrid model will try to predict the current price of the package using the date, package name and external data. A deep leaning model is used to predict the

price of 75 packages and Ordinary Least Squares Multiple Regression (statsmodels) for other 3. Price of 11 packages was not predicted due to reasons explained in the next sub section.

Finding better price

For finding the better price a linear interpolation function was used. Here unique deflated price of packages is used as independent variable and number of sales for that price as dependent variable. Prices were adjusted for inflation of year 2018 as it was the latest year with data.

Selecting the interpolation method

To select the best interpolation method a cross validation was by using all the datapoints available for each package. First a single data point was selected. Then the linear, quadratic and cubic interpolation functions were generated using the remaining datapoints. After that the volume of sales was predicted for the excluded datapoint. Finally the interpolation function with least root mean square error was selected as the best interpolation method for the package. Table 3.6 shows the first 15 packages with their cross validation errors for first 2 data points. Full table is available at appendix C.1.

Package	Y	Linear	Quadratic	Cubic	Best	Y	Linear	Quadratic	Cubic	Best
1	1678	2927.292458	247.3242173	-971.3438714	Linear	428	630.907586	446.9102504	294.9050239	Cubic

15	473.0578001	1780.095517	1675.92193	Linear

Table 3.7: Total error of interpolation methods and best interpolation function for each package

Table 3.7 shows that the interpolation method with least error is Linear Interpolation. If the package contained one or two data points cross validation method can't be applied. Therefore no interpolation method was selected for those 11 packages.

Calculating a better price Figure 3.11 show the overview of the better price calculating process. First the input price was adjusted for inflation[32] and then checked to confirm that it is inside the bounds of the interpolation function. Then using linear interpolation, sales for the input price was calculated. Using the sales and the price current revenue was estimated. Then the price is iteratively incremented to get the maximum revenue better than the current revenue until the upper bound of the interpolation function reached. Then the price which will give a better revenue is returned as better price after readjusting for the inflation. If no better revenue can be calculated current price is assumed to be the best price.

Here only the prices which are higher than the predicted price was used because researchers were unable to gain access to data about cost of each package. Therefore if the better price is actually less than the cost of package, there will be a loss of revenue instead of projected increase of revenue. By considering higher prices this risk can be mitigated.

When there is only one or two data points it is not possible to find a better price using this method. Therefore 11 packages with one or two data points was considered to have insufficient data for price prediction.

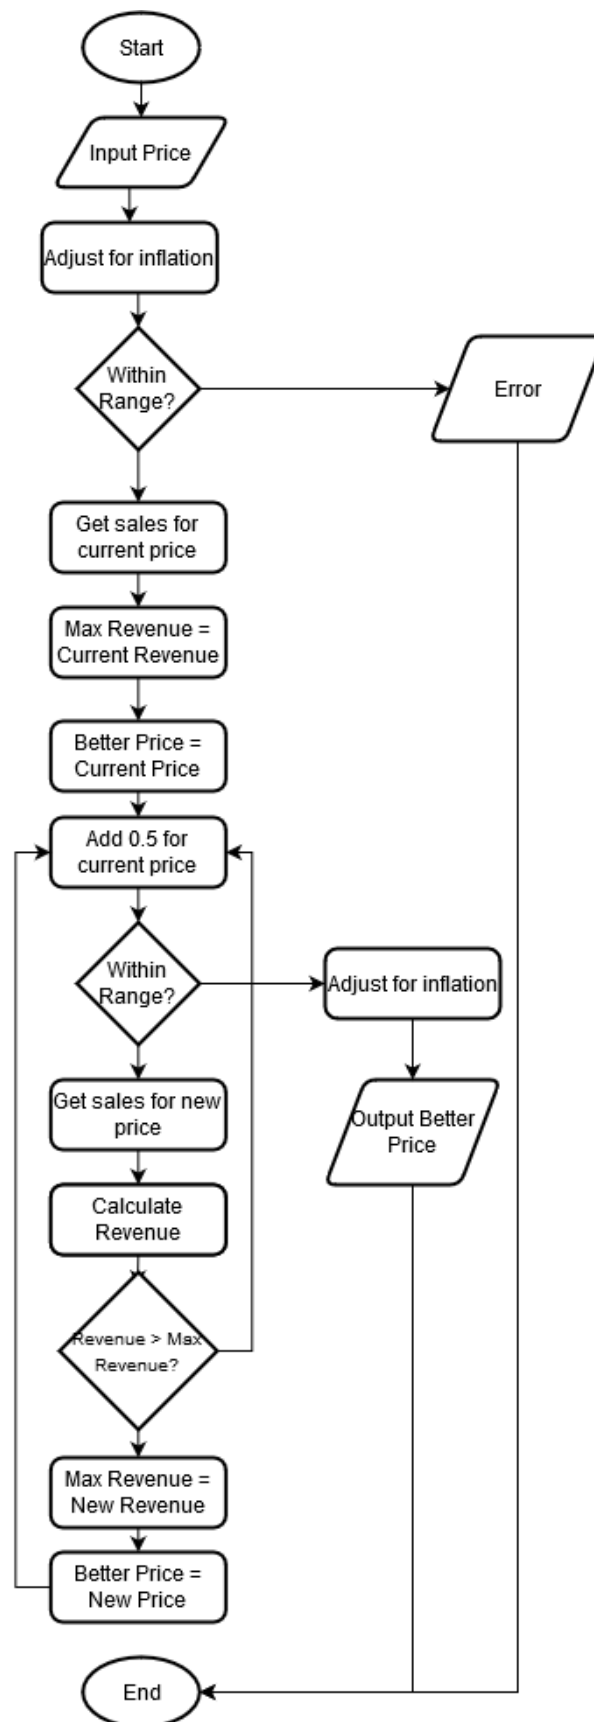

Figure 3.11: Process of calculating better price

3.4.10 Testing the Hybrid Model

The hybrid model was tested by comparing the revenue from unique prices of each package to revenue from using the correspondingly better price. Table 3.8 shows the revenue increase percentage of first 15 packages. Full table can be found in the appendix C.3.

More about the performance of hybrid model is discussed in the Chapter 4 Results and Evaluation.

Package Number	Percentage Increase of Revenue
1	47.93%
2	50.00%
3	100.27%
4	100.27%
5	84.80%
6	120.59%
7	91.12%
8	34.65%
9	34.65%
10	85.77%
11	84.81%
12	120.58%
13	90.09%
14	72.04%
15	112.63%

Table 3.8: Percentage increase of revenue from better prices

Chapter 4

Results and Evaluation

4.1 Introduction

We aimed at finding a better price for trip packages of Flam Railway by considering the external factors weather, season and holidays. In order to study how other factors affect the price we studied and plotted the relationship between other main factors to the price.

4.2 Identify Trip Packages

For the purpose of categorizing the locations where customers travel uniquely, we determined a special category called trip packages which explains the sequence of the route or the stations that customers ordered as a trip. These trips are uniquely identified by “TripID” and it was generated automatically when a customer booked a trip. We derived the Distinct TripIds from the provided database and there were over 3.1 Million TripIds recorded. After that, the First Departure location and the Last Departure location were found among all stations that customers selected as the start and the end stations of the journey. We also found the Arrivals and Departure Locations that have been recorded among the journey which was described in the sample table given below (Figure 4.1).

	Id	FirstDepartureLocation	LastArrivalLocation	DepartureLocation	ArrivalLocation
1	2276221	MYR	FLAM	REI	KJO
2	2276221	MYR	FLAM	HAR	LUN
3	2276221	MYR	FLAM	LUN	FLAM
4	2276221	MYR	FLAM	MYR	VAT
5	2276221	MYR	FLAM	VAT	REI
6	2276221	MYR	FLAM	KJO	BLO
7	2276221	MYR	FLAM	BER	HAR
8	2276221	MYR	FLAM	BLO	BER
9	2276222	MYR	FLAM	BER	HAR
10	2276222	MYR	FLAM	REI	KJO

Figure 4.1: Sample Trip Data

To determine the unique trip packages, initially, the distinct TripIds and their first

departure location were selected. Then the first departure location was taken as the first record from departure location and then the corresponding arrival location was taken. Then that arrival location was used to find the next departure location and then the corresponding arrival location was taken. Likewise according to that algorithm until the last arrival location is the Arrival location the loop would run and finally the trip package could be retrieved.

By processing all 3.1 million distinct Trip Ids from the 12.4 million Ids, 89 Trip Packages were identified.

4.3 Identify the impact on external factors

To identify more on how the external factors weather, season and holidays vary with the price and the relationships of them to the price we have generated graphs as below.

We took the mean price as the y-axis as it would show a clear value and a graph for each and every value from the external factor in the x-axis.

Firstly to get an idea of how the variables relate and vary according to the price we plotted how mean price varied with the weather factors average temperature, total snowfall, amount of sun hours and UV index as shown below.

Temperature

Below shows how mean Price varies with Average Temperature in Celsius (Figure 4.2).

Figure 4.2: Average Temperature Vs Mean Price

This (Figure 4.2) shows that when the average temperature is less than 0 price doesn't increase or decrease drastically and is in the same range but when the average temperature increases from 0 price increases.

Snow Fall

Below shows how mean Price varies with Total SnowFall in cm (Figure 4.3).

Figure 4.3: Snow Fall Vs Mean Price

This (Figure 4.3) shows that Price has increased rapidly when Total SnowFall in cm is about 8.0cm.

Sun Hour

Below shows how mean Price varies with Amount of sun hours (Figure 4.4).

Figure 4.4: Sun Hour Vs Mean Price

According to different amounts of sun-hours mean price has varied between 130 and 200.

UV Index

Below shows how mean Price varies with the UV index.

According to different values of the UV index mean price has varied between 150 and 200 (Figure 4.5).

Figure 4.5: UV Index Vs Mean Price

Season

Next, it was identified how the mean price varies with the season. For better visualization, a bar graph is used (Figure 4.6).

Figure 4.6: Season Vs Mean Price

From this (Figure 4.6), it can say that Trip Package prices are higher in summer when compared to other seasons.

Holidays

Next, it was identified how the mean price varies with the trip date being a holiday or not. For better visualization, a bar graph is used (Figure 4.7).

Figure 4.7: Holiday Vs Mean Price

From this (Figure 4.7), it can clearly say that prices have not increased because of holidays. The main reason for the results provided above, it is only consider the reserved trip data but not the requests for the reservation. According to the Flam Railway [1], as a highly tourist attractive there is a high demand for the reservations. Because of that, Trips are reserved everyday without any shortage or difference on holidays. Because of that, considering the trip reservation data, price variations for Holidays couldn't be observable. (By considering reservation requests for the each and every trips, variations for the demands for trip reservations would be observable.)

4.4 Data Analyzing

Root Mean Square error (RMSE), Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) for each package are as below

Chapter 5

Discussion

5.1 Introduction

Train travelling is increasing day by day as it is a cost effective and also a quicker way of travelling. People in European regions now like to go on trips by train. Therefore train trip offering companies has a good opportunity. For these companies in order to get good revenue they need to identify a better price for each and every trip package they offer. To cater this we have used machine learning and statistical models to predict a better price.

5.2 Findings

- SARIMAX Model was the model with the least mean square error. But it was not suitable for the prediction of future prices and involve significant amount of assumptions when used.
- There were 75 packages whose price was best predicted using deep neural network.
- There were 3 packages whose price was best predicted using Ordinary Least Squares Multiple Linear Regression(statsmodels).
- There were 11 packages with too little data to get an estimation for a better price.
- Maximum estimation of increase of revenue when using forecasted better prices was 120.59%
- Minimum estimation of increase of revenue when using forecasted better prices was 120.12%
- Average estimation of increase of revenue when using forecasted better prices was 79.25%

5.3 Discussion

According to our dataset the number of records for each trip package and the number of distinct prices in each trip package varies as below (Figure 5.1 and Figure 5.2).

Figure 5.1: Number of Trip Records

The Full table can be found on Table A.1 on Appendix Chapter

Figure 5.2: Distinct Prices

The Full table can be found on Table A.2 on Appendix Chapter

When Pearson's Correlation Coefficient calculated the relationship between the number of records for each package and number of unique prices for each package with Root Mean Square Error, a coefficient of -0.43658 and -0.3557 received. This means that there is a weak connection between Root Mean Square Error and number of records for each package and Root Mean Square Error and number of unique prices for each package. Below shows how mean absolute error and root mean square error change for each of the models we implemented.

Deep Neural Network

When considering the results of deep neural network, line graphs of Root Mean Square Error Mean Absolute Error and Mean Absolute Percentage Error are as follows (Figure 5.3, Figure 5.4 and Figure 5.5).

Figure 5.3: RMSE of Deep Neural Network

Figure 5.4: MAE of Deep Neural Network

Figure 5.5: MAPE of Deep Neural Network

Ordinary Least Squares Multiple Linear Regression(sklearn)

When considering the results of Ordinary Least Squares Multiple Linear Regression(sklearn), the line graphs of Root Mean Square Error Mean Absolute Error and Mean Absolute Percentage Error are as follows (Figure 5.6 , Figure 5.7 and Figure 5.8).

Figure 5.6: MAE of Ordinary Least Squares Multiple Linear Regression(sklearn) Model

Figure 5.7: RMSE of Ordinary Least Squares Multiple Linear Regression(sklearn) Model

Ordinary Least Squares Multiple Linear Regression(statsmodels)

When considering the results of Ordinary Least Squares Multiple Linear Regression(statsmodels), the line graphs of Root Mean Square Error Mean Absolute Error and Mean Absolute Percentage Error are as follows (Figure 5.8).

Figure 5.8: MAE of Ordinary Least Squares Multiple Linear Regression(statsmodels)

Figure 5.9: RMSE of Ordinary Least Squares Multiple Linear Regression(statsmodels)

SARIMAX (Time series)

When considering the results of SARIMAX model which is a time series model, the line graphs of Root Mean Square Error Mean Absolute Error and Mean Absolute Percentage Error are as follows (Figure 5.10 , Figure 5.11).

Figure 5.10: MAE of SARIMAX

Figure 5.11: RMSE of SARIMAX

Support Vector Regression (SVR)

In Support Vector Regression there are 3 sub models and below shows how Root Mean Square error changes for the 3 sub models.

RBF Model

Root Mean Square Error (RMSE)

Figure 5.12: RMSE of RBF Model of SVR

Polynomial Model

Root Mean Square Error (RMSE)

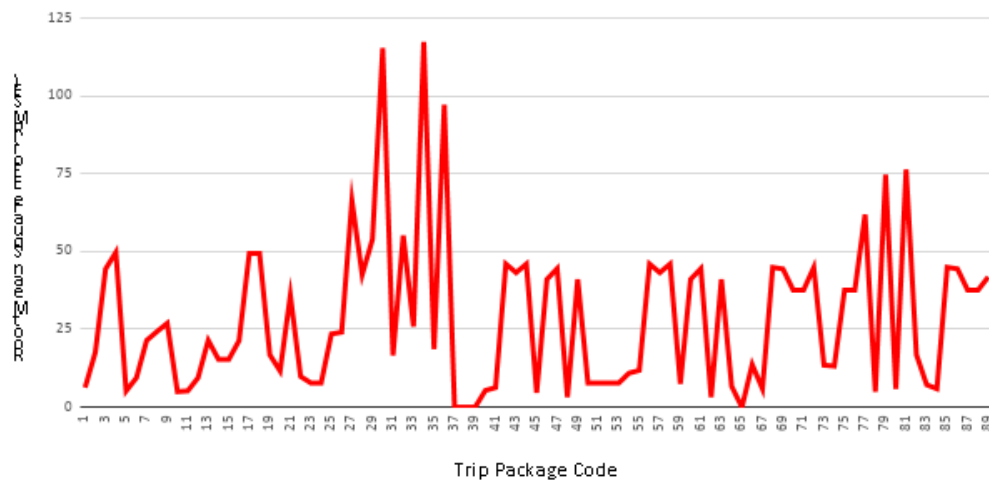

Figure 5.13: RMSE of Polynomial Model of SVR

Liner Model

Root Mean Square Error (RMSE)

Extreme Learning Machine (ELM)

Accuracy of the Prediction (ELM)

Figure 5.15: RMSE of Linear Model of SVR

Hybrid Model

Hybrid model consists of two parts. First part will decide which model to be used to price prediction and predict a price for the package for the given day. This predicted price is the equivalent of the manual price allocated by the Flam railways staff.

The two models used in this part is the deep neural network and Linear Regression model implemented with statsmodels library.

The second part of the hybrid model will calculate a better price than the predicted price using past sales data and deflated prices using a linear interpolation function.

This hybrid model is capable to

5.4 Comparison

Based on the above models below shows the final comparison of the models using the Root Mean Square Error and the best suitable model to predict the trip price for each trip package.

Figure 5.19: Comparison Chart 4

5.5 Conclusion

Least Root Mean Square Error for most of the packages was recorded by Time Series Model. But it is not suitable for the prediction of non-continuous data.

Therefore next best model was the Deep Neural Network. DNN had the least root mean square error in 75 packages. Next was Ordinary Least Squares Multiple Linear Regression(statsmodels) model with 3 packages. In the packages which were discarded due to the lack of data points, linear regression model resulted the least root mean square error. This is due to one or two datapoints present in the dataset.

As there is a weak relationship between Root Mean Square Error, number of records for each package and number of unique prices for each package, we can hypothesize that with a bigger dataset, error can be reduced in the Deep Neural Network.

Hybrid model resulted in average of 79.25% increase of approximated revenue while minimum and maximum increase of improvement is 12.12% and 120.59% respectively. Therefore hybrid model was able to achieve significant increase of revenue to the company.

5.6 Future Work

- Considering more external factors that can affect the price of a trip package will increase the accuracy of data prediction.
- Including the cost for each package will improve the calculating better price.
